Abstract

Context: The medicinal plants used in the traditional medicine of Rivers State of Nigeria were surveyed.

Objective: The survey aims to identify and document the plants used amongst the indigenes of Rivers State.

Materials and methods: Semi-structured interviews were conducted during a field trip to gather information from traditional medical practitioners (TMPs) and community elders.

Results: Medicinal plant species (188) representing 169 genera and 82 families used in the ethno medicine of the people of Rivers State were recorded from 460 households. The most represented genera were *Ipomoea* and *Citrus* providing four species each. The most important species showed the highest Fidelity level (FL) value and these included *Ageratum conyzoides* L. (Asteraceae) (100%) and *Tridax procumbens* L. (Asteraceae) (100%). The most important categories of diseases were those that showed the highest Informant consensus factor (ICF) value of 0.99, such as dermal or digestive problems and fever/malaria. The most used plant part was leaves (42%), while decoction was the main method of drug preparation (36%).

Discussion and conclusion: The survey shows that more than half of the medicinal plants gathered in Rivers State are also used in other countries of the world for various ailments. The high values of ICF recorded indicate high degree of agreement among the informants, while the high FL values suggest the popular use of the plants. The survey provides a useful source of information for TMPs and medicinal plant researchers. These medicinal plants gathered may bring about drug discovery and may also be incorporated into the healthcare delivery system of the country.

Keywords: Ethno medicine, medicinal plants, traditional medical practitioners, dermal problems, digestive problem

Introduction

Throughout the ages people have turned to herbal medicine for healing. All cultures have folk medicines that include the use of plants and plant products. Traditional medicine is becoming more the mainstream as improvement in analysis and quality control alongside advances in clinical research show the value of traditional medicine in the treatment and prevention of diseases (Kraft, 2009). Alternative medicine emphasizes therapies that improve quality of life, prevent disease, and address conditions that modern medicine has limited success in curing (Blackman, 2008). Traditional systems of medicine – both organized (e.g., Ayurveda and Chinese traditional medicine) and unorganized (herbalism) – using medicinal

plants as the raw material is crucial to indigenous people in the developing countries of the world (Bannerman, 1979; Rastogi & Dhawan, 1982).

The World Health Organization (2002) estimated that about 80% of people worldwide rely on herbal medicine for some part of their primary health care. A similar percentage of the Nigerian population was reported to employ traditional medicine for their primary health care (Sofowora, 1991; Ajibesin et al., 2008). Traditional medicine is gaining prominence in view of new or resistant and challenging ailment which modern medicine has not been able to address, and the total care approach of traditional medicine. In wealthy nations, a growing number of patients rely on alternative medicine for preventive or

(Received 02 September 2011; revised 17 January 2012; accepted 25 January 2012)

palliative care. In France, 75% of the population has used complementary medicine at least once, in Germany, 77% of pain clinics provide acupuncture and in the UK, expenditure on complementary and alternative medicine stands at USD 2.3 million per year (WHO, 2002). In the US, public dissatisfaction with the cost of prescription medications, combined with an interest in returning to natural or organic remedy results in an increase in the use of herbal medicine (Moquin et al., 2009). Global estimate of herbal medicine business has been put down to about USD 60 million (NNMDA, 2006).

Traditional medicine is generally transmitted orally through a community, family, or individuals. However, such knowledge is scarcely documented in developing countries and this may result in distortion or loss of the entire knowledge. Hence, this study aims to identify and document medicinal plants used in traditional medicine of Rivers State of Nigeria.

Materials

Study area

Rivers State is situated in the oil rich Niger Delta Region of Nigeria (Figure 1). It is bounded on the South by the Atlantic Ocean, to the North by Imo, Anambra and Abia States, to the East by Akwa Ibom State and to the West by Bayelsa and Delta States (Anonymous, 2003). The State covers a total land area of 11,077 km² and lies between latitudes 4° 45' N and longitudes 6° 50' E. The inland part of the State consists of tropical rainforest, while mangrove forest, a characteristic of the Niger Delta environment dominates the coast (Anonymous, 2003).

Rivers State consists of twenty-three Local Government Areas with a population of about 6,689,087. The State is made of four major ethnic groups: Ikwerre, Ekpeye, Kalabari and Ogoni, from which other minor ethnic groups emerged such as Abua, Andoni, Engenni, Etche, Ibani, Igbari, Ndoni, Ogbia and Okrika. Thus, the languages of the four major ethnic groups are spoken throughout the State.

The people of Rivers State are of diverse tribes and languages, whose chief occupations are fishing for those living in the riverside areas, and farming for those in the upland areas. However, the urban dwellers embark on commerce and industry. The people also produce fired clays and bronze. Majority of the people live in the rural areas (about 72%) and are bonded culturally by music, dances, plays and masquerades (Anonymous, 2003).

Rivers State has one of the largest economies in Nigeria, mainly because of its crude oil. The State has two major refineries, two major seaports, airports and various industrial spread across the State.

Mode of information collection

The ethno medicinal survey was undertaken between January and December 2010. Information on data such as local names, plant part used, therapeutic effect, diseases treated, method of preparation and method of

administration, doses and duration of treatment was gathered through semi-structured questionnaires amidst informal conversation (Huntington, 2000). Interviews were administered individually on traditional medical practitioners (TMPs) and community elders in all the Local Government Areas of Rivers States (Figure 1). All the TMPs interviewed were those available in all the Local Government Areas, while the selection of community elders was based on the recommendation of the respective community head. The basic method followed was a guided field interview (Martin, 1995; Maundu, 1995). The informants were conducted during the day on field trips to areas where they often collected plants, while survey interviews which included questions such as what ailments were treated by what plant species were simultaneously asked and information taken. The information obtained was noted while in the field and later cross checked with the informants at evening meetings, which usually

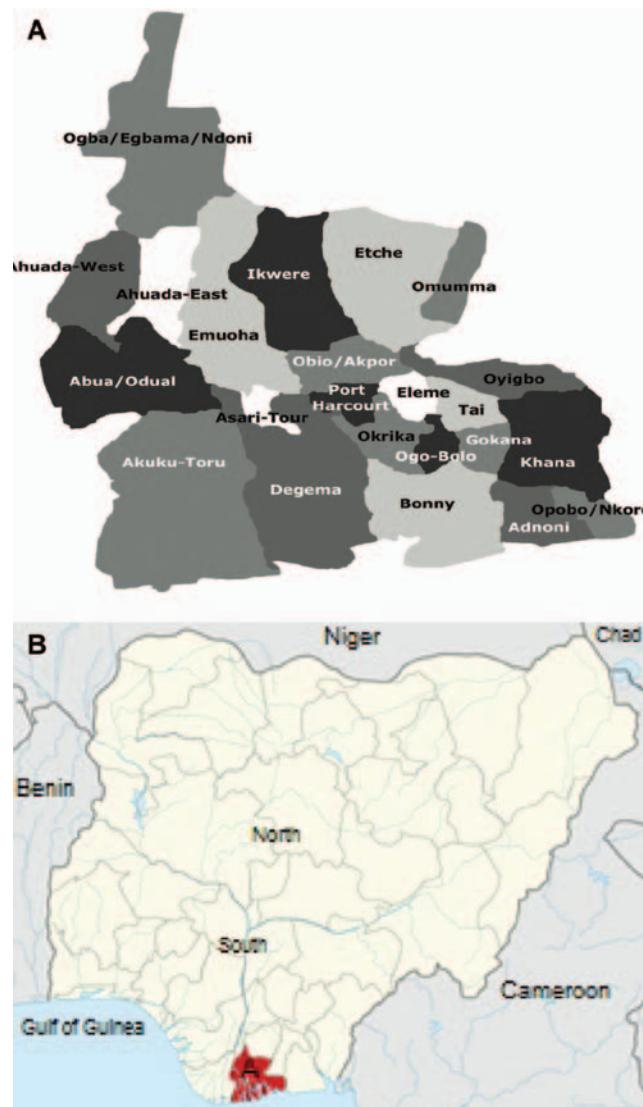

Figure 1. (A) Map of Rivers State showing the Local Government Areas surveyed. Map of Nigeria. (B) (shaded portion): Rivers State.

comprised the TMP, community elders and any other interested persons. Informed consent was obtained from every informant prior to the interview. Interviews were conducted with the aid of an interpreter throughout the survey. The survey covered all the local government areas of the State (Figure 1).

Medicinal plants mentioned were collected, identified and subsequently preserved and stored in the herbarium of the Department of Pharmacognosy and Natural Medicine, Faculty of Pharmacy, University of Uyo.

The plants were identified by the use of flora of Nigeria and West Africa, and their taxonomy was further established by the use of International Plant Names Index Database and African Plants Database (Hutchinson & Dalziel, 1954, 1958, 1968; Keay et al., 1964; Stanfield & Lowe, 1987; Anonymous, 2008, 2009), as well as by the use of other publications on medicinal plants (Iwu, 1986, 1993; Ajibesin et al., 2008).

Biodiversity rights of the indigenes were protected. Aerial parts of the plants were collected on a sustainable basis so as to preserve the lives of the plants. Where collection of roots was involved, new plants were cultivated for sustenance of biodiversity.

Data analysis

Informant consensus factor

The reported diseases were grouped into twelve categories based on the information gathered from the respondents. The categories were: parasitic, viral and bacterial diseases; dermal system; digestive system; musculoskeletal and articular system; nervous system; reproductive system; respiratory system; stings/bites; fever/malaria; urinary system; cardiovascular system and others such as anemia, diabetes, ear infection and eye infection. Informant consensus factor (ICF) was calculated for each category of ailments to identify the agreements of the informants on the reported cures for the group of ailments. ICF was calculated as follows:

$$ICF = \frac{(N_{ur} - N_t)}{(N_{ur} - 1)}$$

where N_{ur} is the number of use citations in each category and N_t is the number of species used (Heinrich et al., 1998).

Fidelity level (FL)

Fidelity level was also used to analyze the data. It was calculated for the most frequently reported diseases as:

$$FL(\%) = \frac{N_p}{N} \times 100$$

Where N_p is the number of informants that claim a use of a plant species to treat a particular disease and, N is the number of informants that use the plant as a medicine

to treat any given disease (Alexiades, 1996). This method helps in selecting medicinal plants for further study.

Results

Knowledge of informants and medicinal plants

Four hundred and sixty informants provided information on remedies used to treat 61 ailments (Table 1) in Rivers State, of which 70% were male and 30% female. Their mean age was 65 years. All the healers available for survey (222 TMPs) were male and reported both single and multiple medicinal plants treatment of diseases; whereas the non-healers (238) who were a mix of male and female reported only single medicinal plant remedies (Table 1).

The number of ethno medicinally important plant species documented in Rivers State was 188, belonging to 169 genera and 82 families. The number of medicinal use reports recorded was 54,479 (Table 2). The plants were arranged in the alphabetical order of their families. Local names were provided in four major ethnic languages: Ikwerre, Kalabari, Ogoni, and Ekpeye.

The ten most important plant families in terms of their number of taxa were recorded as Lamiaceae (11), Asteraceae (10), Euphorbiaceae (8), Cucurbitaceae (7), Papilionaceae (7), Rubiaceae (7), Liliaceae (6), Malvaceae (5), Solanaceae (5) and Rutaceae (5) (Figure 2). The most represented genera were *Ipomoea* and *Citrus* providing four species each.

Plant parts used, methods of preparation and administration

The most frequently used plant part was the leaves (42.24%), followed by root (7.36%), bark (7.36%), whole plant (7.36%), seed (6.58%), fruit (6.20%) and stem (4.65%). The other plant parts were rarely mentioned (Figure 3).

Plant remedies were prepared mainly by decoction (36.22%) followed by infusion (24.85%), juice (20.05%) and poultice (11.37%) (Figure 4). The internal method of administration which was largely oral was more common (70.83%) than the external method which was usually topical or bathing (23.56%). Other routes of administration (5.61%) such as eye drop, ear drop, chewing and gargle were also applied.

Importance of ailments treated

Diseases relating to the dermal system, digestive system, fever/malaria, parasitic, viral and bacterial diseases, and musculoskeletal and articular diseases were among the most frequently treated diseases with medicinal plants, representing 67.92% of all the medicinal applications (Table 2). Of this, the largest number of remedies was employed to treat diseases relating to the dermal system (22.07%), followed by digestive problem (15.88%) and fever/malaria (11.73%).

About 32 combinations of medicinal plants were utilized to treat various external and internal ailments (Table 1). Of the multiple plant treatments, 47% contained

Table 1. Medicinal plants of Rivers State.

Family	Botanical name	Specimen number	Local name	Plant part used ^b (sources)	Method of preparation	Ailment treated, therapeutic effect	Administration, dosage, duration of treatment	Fidelity Level	Reported ethno botanical uses ^c
Acanthaceae	<i>Justicia shimpéri</i> (Hochst.) Danby	PNM 1	Ekpegwo (Kalabari)	Leaves (12,13,16,18, 19,21)	Decoction	Chest pain, heart failure	Internal use: 3 x 1 till relief	61

leaves and were prepared by mixing the ingredients in different proportions.

Informant consensus factor

The medicinal plants presumed to be efficacious in treating a certain disease showed higher ICF values. Table 2 indicates disease categories with ICF values. Disease categories such as dermal, respiratory, fever/malaria,

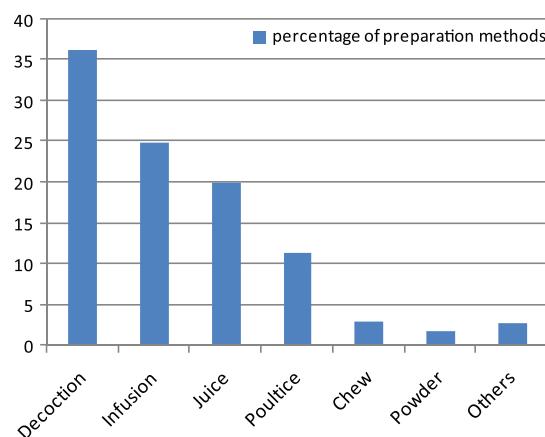

Figure 4. Percentage occurrence of methods of preparation.

urinary and cardiovascular systems have relatively higher values (0.99).

Fidelity level (FL)

Fidelity level is the percentage of informants claiming the use of a certain plant for the same purpose. Table 1 indicates the FL for all the medicinal plant species collected to treat various specific ailments. Plant species such as *Daucus carota* L. (Apiaceae) and *Ageratum conyzoides* L. (Asteraceae) gave the highest FL value of 100%, while *Musa paradisiaca* L. (Musaceae) provided the lowest FL value of 19%.

The highest number of plant species employed to treat diseases belong to the family Lamiaceae, suggesting that it is the most important family in the traditional medicine of the State. The other important families in terms of number of taxa with medicinal uses in the State were Asteraceae, Euphorbiaceae, Cucurbitaceae, Papilionaceae, Rubiaceae, Liliaceae, Malvaceae, Solanaceae, and Rutaceae. These families feature saliently in the traditional medicines of other parts of Nigeria, and are reported in the flora and pharmacopoeia

of the country (Nyananyo, 2006; NNMDA, 2006, 2008; FMH, 2008). These families are usually considered during ethno botanical approaches to drug discovery due to their rich content of secondary metabolites such as steroids, terpenes and alkaloids (Desmarchelier & Witting-Schaus, 2000). The previous ethno botanical survey on one of the States in the same Niger Delta Region also revealed that Euphorbiaceae was among the most important families (Ajibesin et al., 2008). A recent study among the people of Zegie in Ethiopia reported Euphorbiaceae and Asteraceae to be among the most important families used by the community (Teklehaymanot & Giday, 2007).

Lamiaceae is of particular importance to the State. Eleven species were cited for medicinal use by the informants. The plant species of the family were indicated in the treatment of virtually all the diseases of the most important categories recorded. This may be due to their volatile oil content which is known to treat a vast number of diseases. Lamiaceae was also reported as the most prevalent family in the flora of Ethiopia and Eritrea (Ryding, 2006).

In this study, leaves were the most common plant part used followed by root, bark and seed. The reason for the widespread use of leaves may be due to the ease of obtaining them. The leaves remain lush and abundant for most part of the year since the State receives rainfall for about eight months of the year. Leaves have been observed as the most widely used plant part in many ethno botanical studies (Tabuti et al., 2003; Kala, 2005; Muthu et al., 2006; Giday et al., 2009; Hossan et al., 2010). Harvesting leaves for medicinal use ensures plant survival unlike the roots that may threaten its continuity (Lulekal et al., 2008; Yin, 2009), unless a sustainable harvesting strategy has been developed (Cunningham, 2001). The most common method of preparation was decoction followed by infusion and juice. Decoction was also reported as the most prevalent method of preparation in Babungo, Cameroon (Simbo, 2010). Medicines were administered mainly orally through internal use. This may be related to the prevalent use of decoction since decoction is usually administered orally. Generally, this result follows the pattern of medicinal plant use in Africa (Anonymous, 2008, 2009). However, in some other parts of the world, decoction was also indicated as a common method of herbal preparation (Taylor, 2005; Rahmatullah et al., 2010; Sankaranarayanan et al., 2010). The use of single plant in preparing herbal remedies predominates over the multiple plant preparation in this study. This offers the advantage of a relatively safer potion over mixture of plants that may be ill-matched and dangerous for human body system. In the traditional medicine of other countries such as Bangladesh and Peru, single medicinal plants were also observed to treat single or multiple ailments (Hossan et al., 2010; Rahmatullah et al., 2010; Luziatelli et al., 2010). All the remedies in this study were prepared in crude form, thus lacking standardized dosage and quality control (Anonymous, 2008; Nanyingi et al., 2008).

The most frequent categories of diseases treated with medicinal plants in Rivers State based on medicinal use report were dermatological problems, digestive problems and fever/malaria. These categories were also prevalent in the ethno botanical studies undertaken among indigenous people of Fiji, Australia, India, Mexico, Kenya, Haiti, Nicaragua, Peru, Saudi Arabia, Thailand, North America, Tonga and West Africa (Cox, 1994). This implies that these categories of diseases treated in Rivers State with medicinal plants are similar to those encountered by the majority of the rural people in developing countries.

Ailments affecting the dermal system are, among others, skin diseases, wounds, bleeding and burns. These diseases were diagnosed by visual examination. The skin diseases were the most frequently mentioned ailment and were usually cited as skin rashes, skin spots, and eczema. This category is also reported as the most important in Bajo Quimiriki and Yaneshia in Peru (Luziatelli et al., 2010; Valadeau et al., 2010). Problems relating to digestive system include stomachache, diarrhea, dysentery, and worm infestation. These may be caused by the absence of sewage system and infestation of drinking water by eggs of intestinal parasites. Malaria is a major disease treated by the people of Rivers State. The people were aware that malaria was caused by the bite of infected mosquitoes, and diagnosis was by febrile condition. However, diagnosis of malaria by TMPs can be nebulous in certain cases. For instance, an herbalist claimed that he diagnosed malaria by going in a trance where he found the patient swimming in a pool of blood. Malaria is a widespread disease in Brazil treated with various medicinal plants (Botsaris, 2007). Some of these diseases mentioned are the same as those frequently treated in the neighboring Akwa Ibom State (Ajibesin et al., 2008). This is probably due to intercultural diffusion of medicinal plant knowledge between the two States.

Categories of ailments such as dermal system, respiratory system, fever/malaria, urinary system, cardiovascular system and others including specific diseases such as diabetes, anemia, eye infection and ear infection showed the highest ICF. This implies that the diseases of these categories have the highest level of agreement for being treated by medicinal plants. Other categories of diseases also showed relatively high ICF. The medicinal plants that are considered to be efficacious in treating certain diseases have higher ICF. This may suggest high prevalence rate of such diseases in the region, possibly due to poor socio-economic and hygienic conditions of the people. It also suggests that the knowledge of the treatment of the categories of diseases with higher ICF is accessible to both the healers and the elders in this study.

The medicinal plants that are commonly used by the local people have higher FL value than those that are less popular. On the other hand, medicinal plants that treat a single ailment have 100% FL, while those that are used as remedies of more than a single ailment give lower FL value. For instance, *Irvingia gabonensis* is used to treat stomachache, worm infestation, skin disease and

infertility, and its FL value is 40%. A high FL value may also indicate good healing potential of the plants (Giday et al., 2009).

The use of ICF aids in detecting major categories of health conditions for which medicinal plants are used, while through FL, the most important plant species are selected from these categories.

Scientific literature was surveyed to compare the uses of medicinal plants in Rivers State with those of the other parts of the world, so as to validate the uses of medicinal plants reported by informants in this study (Table 1). This indicates their significance in the traditional medicine of other countries. The widespread use of these plants provides a confirmatory evidence of their uses in Nigeria, and this underpins a greater chance of drug discovery, especially when the cultures are totally unrelated.

One hundred and eleven plant species (59%) used by the indigenes of Rivers States are also used in other parts of the world for similar and other ailments. The literature search on ethno pharmacological use showed that many of the medicinal plants with high FL are used to treat ailments in other parts of the world (Table 1). However, those that have low FL because they are used to treat more than one disease are also employed in the traditional medicine of other countries to treat one or more diseases. Although plants with high FL are the most preferred species in study sites (Table 1), plants with low FL should not be neglected as failing to mention them to the future generation could increase the risk of gradual disappearance of the knowledge (Chaudhary et al., 2006).

Ageratum conyzoides L. (Asteraceae) is used specifically to treat skin diseases in Rivers State, thus showing a very high FL of 100%. However, amongst the Mopa ethnic group of India, the plant gave FL of 60% because it is used for more than one ailment. It is used in veterinary medicine, as fish poison and to treat wound (Namsa et al., 2011).

In some African countries, *Ageratum conyzoides* is used as a local remedy to treat diseases such as skin diseases, wound, headache and mental and infectious diseases (Durodola, 1977). In other parts of the world such as Brazil and Vietnam, it is used to treat inflammation and gynaecological diseases (Yamamoto et al., 1991; Sharma & Sharma, 1995).

The plant has been reported to contain flavonoids identified as ageconyflavone A, ageconyflavone B, ageconyflavone C and isoflavones (Adesogan & Okunade, 1979; Vyas & Mulchandani, 1986; Yadava & Kumar, 1999), chromenes (Sharma et al., 1980) and pyrrolizidine alkaloids (Wiedenfeld & Röder, 1991). These compounds may be responsible for the bioactivity of the plant.

Tridax procumbens L. (Asteraceae) is used to treat skin diseases in Rivers State with FL of 100%. The plant also showed FL of 100% in treating swellings by the Kani tribes in India (Ayyanar & Ignacimuthu, 2011). The plant was also reported to cure skin diseases in Akwa

Ibom State, Nigeria (Ajibesin et al., 2008). In Togo, the leaf juice of the plant is used to treat injury, cuts and wounds (Adjanohoun et al., 1986), while the whole plant was reported to stop bleeding in Madagascar (Boiteau, 1986). The plant is also used for other diseases that are not related to the skin such as amenorrhea (Adjanohoun et al., 1986), hypertension (Adjanohoun et al., 1989) and malaria (Kokwaro, 1993).

Flavonoids such as luteolin, glucoluteolin, quercetin and isoquercetin (Ali et al., 2001), and sitosterol (Verma & Gupta, 1988) were identified in the flower of the plant.

Zingiber officinale Roscoe (Zingiberaceae) is used to treat diseases such as hypertension, constipation, cough and stomachache in other parts of the world as it is in Rivers State. The plant gave a low FL of 29% which suggests that the plant is less preferred for the treatment of a specific ailment. However, this FL value was the highest recorded for ginger to treat stomachache, indicating the disease as the most commonly treated by ginger. In Northwest Ethiopia, ginger is used to treat stomachache alone (Teklehaymanot & Giday, 2007). Also, in Egypt, it is used solely to treat common cold, thereby showing 100% FL (AbouZid & Mohamed, 2011). However, in India, the plant was reported to treat cough and throat clearance with FL value of 67% (Namsa et al., 2011). Ginger is in the pharmacopoeias of countries such as China, India, Egypt and Japan. Traditionally, ginger is used in these countries as an acrid bitter to strengthen and stimulate digestion, and to treat stomachache (Langner et al., 1998). It is also used for hypertension and constipation (Ali et al., 2008).

In China, ginger root may be prepared as tea or prepared with scrambled eggs to treat cough (Bensky et al., 2004). Ginger may also be made as candy in fermented plum juice and sugared to suppress cough. In Ethiopia, ginger rhizome is chewed for stomachache (Gedif & Hahn, 2003). In North Africa, olive oil in which powdered rhizome has been soaked for several days is used for rubbing the body, after a birth, for rheumatism (Boulos, 1983). The decoction of the rhizome mixed with equal amount of black pepper, then added into boiling honey, is taken in the form of pellets twice a day, in the morning and at night, against pectoral diseases (Boulos, 1983).

The majority of the medicinal properties of ginger, including hypertensive and cardiotonic properties, have been attributed to pungent vallinoids such as [6]-gingerol and [6]-paradol and other constituents such as shogaols and zingerone (Nigam et al., 2011).

The leaves of *Abrus precatorius* L. (Papilionaceae) are used for eye infection, skin disease, cough and malaria in Rivers State with FL of 44%. Although its FL value was not reported, the root of the plant mixed with cow milk was indicated as a local remedy to treat scorpion sting and snakebite in Tamil Nadu, India (Muthu et al., 2006). The seed is very poisonous when swallowed (Verma et al., 1989). It is so poisonous that external application is done

with great care (Panda, 2004). The toxic principle of the seed has been reported as abrin which may cause blindness or even death (Dickers et al., 2003).

In Trinidad, a tea made from the leaves is used to treat fever, cough and cold (Mendes, 1986). Decoction of the leaf is used in India to wash the eyes early morning for a month to cure poor eye sight (Tirkey, 2006). Leaves are also made into paste in Chattisgarh, India, and applied to the affected parts twice a day for a week to cure any type of skin diseases (Tirkey, 2006). In treating conjunctivitis in Tanzania, the seeds are boiled and the decoction used to bathe the eyes (Chhabra, 1990). In Chinese medicine, the leaf decoction is used to treat fever (Chevallier, 1996; Navarra, 2004), while in Cambodia, it is the seeds that are utilized to treat malaria (Ross, 2003). In Ogun State, Nigeria, the leaf decoction is also used to treat malaria (Idowu et al., 2010).

World Health Organization (1990) reported constituents such as abrin, abralin, N-methyl tryptophan and urease from the plant, while Limmatvapirat et al. (2004) identified isoflavanquinone, abruquinone B from the aerial part of the plant.

Vitex doniana Sweet (Vitaceae) is used to treat diarrhea and dysentery in Rivers State with FL of 56%. In an ethno botanical study of Kainji Lake National Park, Nigeria, the leaves and bark of *Vitex doniana* were reported to cure stomachache (Amusa et al., 2010). The FL of the plant was not provided, but it was reported to occur frequently and its mean density was given as 0.028 ± 0.520 . The plant is used extensively to cure dysentery and diarrhea in the traditional medicines of many countries of Africa. In Southwestern Nigeria, a decoction of the stem bark is taken orally to treat diarrhea (Kilani, 2006). In the same region of the country, the stem bark and branches of *Vitex doniana* are macerated with those of *Lannea welwitschii* (Hiern) Engl. (Anacardiaceae), *Terminalia glaucescens* Planch. ex Benth. (Combretaceae) and *Diodia scandens* Sw. (Rubiaceae), and the potion taken orally to treat diarrhea and dysentery (Adjanohoun et al., 1991). However, in Northern region of Nigeria, the leaves of the plant, mixed with those of *Psidium guajava* L. (Myrtaceae), are macerated to treat diarrhea (Igoli et al., 2005). In Republic of Benin, the plant is mixed with the pulp of *Vernonia doniana* DC. (Asteraceae) to cure diarrhea (Adjanohoun et al., 1989). The root decoction is used in Democratic Republic of Congo for diarrhea and dysentery (Hirt & Bindanda, 1993). The trunk barks, stem with leaves or roots of the plant are prepared separately in Mali to treat infantile diarrhea and leprosy (Malgras, 1992). *Vitex doniana* has also been reported to treat other ailments. The bark of the underground part of the plant is boiled in water to treat constipation in Burundi (Baerts & Lehmann, 1989), while the mixture of its bark and the fruits of *Parkia biglobosa* (Jacq.) R. Br. ex G. Don. (Fabaceae) has long been used in Senegal as a palm wine infusion to cure fever (Thomas, 1972).

Conclusions

The majority of the people in developing countries rely on TMPs and community elders for the treatment of various diseases. Collectively, they possess a vast knowledge of medicinal plant uses. Thus, it is important to collate information on medicinal plants that are used as treatments for diseases. This survey therefore provides a useful source of information for practitioners of traditional medicine and medicinal plant researchers.

A substantial number of medicinal plants used in Rivers State to treat ailments are also used in other regions of the world for similar purposes. These plants provide a basis for investigation by modern scientific methods for possible discovery of novel drugs, which may be incorporated into the healthcare system of the country. A comparison of the survey results with the published scientific reports indicates that some of the plants have had their uses in traditional medicine scientifically validated.

Acknowledgements

The authors acknowledge the contributions of the TMPs and the community elders of Rivers State. We are also grateful to Mr. Okon Abia-Williams, an herbalist in the Department of Pharmacognosy & Natural Medicine, University of Uyo, Uyo, for facilitating contact with the TMPs of Rivers State.

Declaration of interest

The authors declare no conflict of interest.
